## 2. Project Description

### Problem:

Some people find it hard to **prepare a meal**, especially when having limited ingredients.

### Solution:

jomMasak! is an Android application that aids user in preparing a meal. The only thing the user needed is the **list of ingredients possessed**, and the application will **suggest a possible meal** (or maybe more) that can be prepared using those ingredients.

Our team uses mySQL database to store and retrieve information regarding a meal i.e the name of a meal, ingredients and instructions to prepare the meal.

After the user inputs his/her food items, the application will search for a match using mySQL command/query between the items entered and ingredients contained in the database. If there's a match between the user's input and the values in the ingredients table, the app will suggest one or more possible meal suggestions along with its ingredients and instructions.
